Experiment No: 8

Aim: Write a program to implement Threading in python.

Theory:

Multithreading is a threading technique in Python programming to run multiple threads concurrently by rapidly switching between threads with a CPU help (called context switching). Besides, it allows sharing of its data space with the main threads inside a process that share information and communication with other threads easier than individual processes. Multithreading aims to perform multiple tasks simultaneously, which increases performance, speed and improves the rendering of the application.

There are two main modules of multithreading used to handle threads in Python.
The thread module
The threading module

Thread modules

It is started with Python 3, designated as obsolete, and can only be accessed with **_thread** that supports backward compatibility.

Syntax:

   1. thread.start_new_thread (function_name, args[, kwargs])

To implement the thread module in Python, we need to import a **thread** module and then define a function that performs some action by setting the target with a variable.

Threading Modules

The threading module is a high-level implementation of multithreading used to deploy an application in Python. To use multithreading, we need to import the threading module in Python Program.

Thread Class Methods

Methods Description	
start()	A start() method is used to initiate the activity of a thread. And it calls only once for each thread so that the execution of the thread can begin.

run()	A run() method is used to define a thread's activity and can be overridden by a class that extends the threads class.
join()	A join() method is used to block the execution of another code until the thread terminates.

Follow the given below steps to implement the threading module in Python

Multithreading: **1. Import the threading module**

Create a new thread by importing the **threading** module, as shown.

Syntax:

1. **import** threading

A **threading** module is made up of a **Thread** class, which is instantiated to create a Python thread.

2. **Declaration of the thread parameters:** It contains the target function, argument, and **kwargs** as the parameter in the **Thread()** class.

- o **Target**: It defines the function name that is executed by the thread.
- o **Args**: It defines the arguments that are passed to the target function name.

Start a new thread: To start a thread in Python multithreading, call the thread class's object. The start() method can be called once for each thread object; otherwise, it throws an exception error.

Syntax:

1. t1.start()
2. t2.start()

4. Join method: It is a join() method used in the thread class to halt the main thread's execution and waits till the complete execution of the thread object. When the thread object is completed, it starts the execution of the main thread in Python.

5. Synchronizing Threads in Python
It is a thread synchronization mechanism that ensures no two threads can simultaneously execute a particular segment inside the program to access the shared resources.

PROGRAM

```python
import threading
import time

# Define a function that will be executed in a separate thread
def print_numbers():
    for i in range(5):
        print("Number:", i)
        time.sleep(1)  # Sleep for 1 second between each iteration

# Define a function that will be executed in another separate thread
def print_letters():
    for letter in ['a', 'b', 'c', 'd', 'e']:
        print("Letter:", letter)
        time.sleep(1)  # Sleep for 1 second between each iteration

# Create threads for each function
thread1 = threading.Thread(target=print_numbers)
thread2 = threading.Thread(target=print_letters)

# Start the threads
thread1.start()
thread2.start()

# Wait for both threads to finish
thread1.join()
thread2.join()

print("Both threads have finished executing.")
```

OUTPUT:

```
PS C:\Users\Lenovo\Downloads\Python Prgs> python -u "c:\Users\Lenovo\Downloads\Python Prgs\thread.py"
Number: 0
Letter: a
Number: 1
Letter: b
Number: 2
Letter: c
Number: 3
Letter: d
Number: 4
Letter: e
Both threads have finished executing.
PS C:\Users\Lenovo\Downloads\Python Prgs>
```

Conclusion:

The experiment successfully demonstrated the implementation of threading inPython, showcasing its ability to execute multiple tasks concurrently and improve program efficiency. Through this exercise, the benefits of threading in enhancing performance and resource utilization were clearly evident, emphasizing its importance in modern software development.
